

Description of the module Fancy Theorems

Udi Fogiel

Abstract

With the module *Fancy Theorems* you can modify all the theorems layouts output appearance (except the proof and case layouts), using a key-val syntax much like in thmtools. All the theorems environments are defined using the L^AT_EX package **fancythm**, which rely heavily on the L^AT_EX package **thmtools**. It is recommended to read some of **thmtools** documentation.

1. Preparation

1.1. Installation

Firstly, manually install the `fancythm` package. The installation procedure is dependent on your \LaTeX distribution, so I won't explain how to do so here (it will probably just require you to copy the `fancythm` folder to some directory, and then tell your latex \LaTeX distribution that you added a new folder to it's directories).

To install the module *Fancy Theorems*, move the file `fancythm.module` to the layouts folder in LyX's user directory (which can be found in **Help**▷**About Lyx.**). After that reconfigure LyX via **Tools**▷**Reconfigure**, and restart LyX.

Note that the \LaTeX package `fancythm` requires the packages `amsthm`, `thmtools` and `multicols`. If the `templates` option is used, also `fancythm` also loads `xcolor` with `usenames` and `dvipsnames` options, `tikz` with the `decorations.pathmorphing` and `shadows` libraries, `varwidth`, `tcolorbox` with the `most` option. It is recommended to check that all of these packages are installed.

1.2. Loading The Module

At first load the module *Fancy Theorems* in the document settings of your file, via **Documents**▷**Settings**▷**Modules**.

If you want to use the `templates` option, write “templates” in the document class options in the document settings of your file.

2. Basics

2.1. Designing Theorems

Suppose you would like to state the Pythagorean theorem in your document. To do so, go to LyX's environment selection combobox, select the Theorem layout and write the theorem's content (if you would to write an optional note, go to **Insert**▷**Optional Note**, or press **Alt+A 1**).

Theorem 2.1 (Pythagoras). *In any right triangle, the area of the square whose side is the hypotenuse (the side opposite the right angle) is equal to the sum of the areas of the squares whose sides are the two legs (the two sides that meet at a right angle).*

To change the appearance of the theorems in the output PDF file insert the **Set Keys** layout via **Insert**▷**Custom Insets**▷**Set Keys**, in the argument inset (called `envs`) write a comma separated list of all the environments names that you want to change (for a list of all the environments names see [subsection 3.2](#)), and in the inset itself write the keys with the appropriate values. For example, we will change the note braces to be square brackets, we will add a symbol to mark the end of the theorem and add more vertical space before the theorem.

Now we should be able to see the changes in all the following theorems (with environment name `thm`).

Theorem 2.2 [Pythagoras]. *In any right triangle, the area of the square whose side is the hypotenuse (the side opposite the right angle) is equal to the sum of the areas of the squares whose sides are the two legs (the two sides that meet at a right angle).* ★

! The latex command of that layout is `\setfancymkeys{<envs>}{<key=val>}`, where `<envs>` is a comma separated list of all the environments names that you want to change, and `<key=val>` is a comma separated list of the keys you want to change. In addition, `<envs>` accepts the keywords **all**, **reg**, and **strd** to apply the changes to all environments, all the unstarred variants, or all the starred variants.

The following diagram¹ demonstrates some of the possible theorems keys.

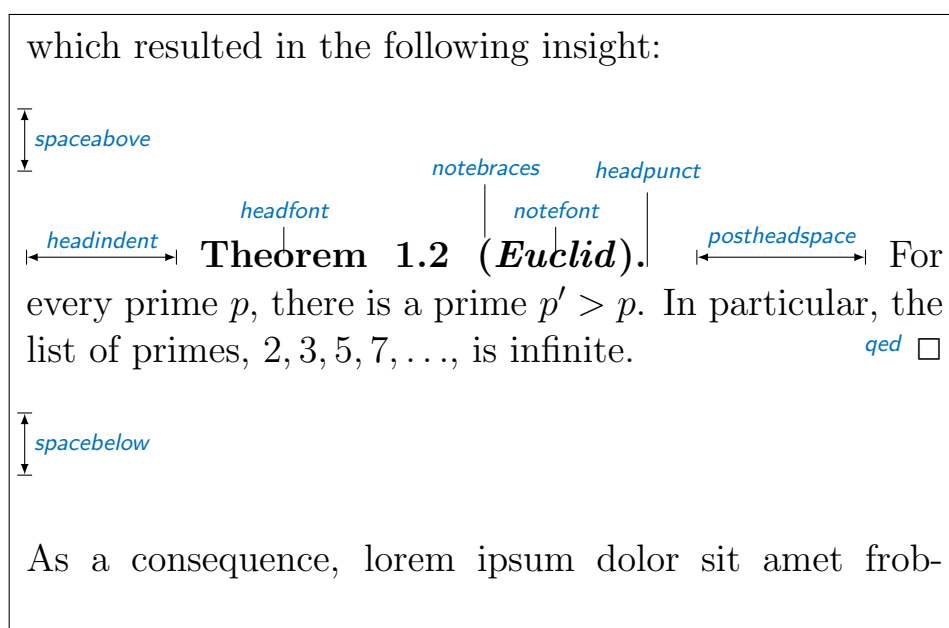

Figure: Settable parameters of a theorem style.

For a full list of keys and their description, see [subsection 3.1](#).

There is an option to use preview box (via **Insert**▷**Preview**) with the theorems layouts, but, to see the changes that you applied you need to include the **Set Keys** layout in the preview box, or, set the keys in the preamble (and make sure that **Tools**▷**Preference**▷**Look & Feel**▷**Display**▷**Instant Preview** is on).

! For example, this paragraph is written with the Remark* layout (its keys are set in the preamble) inside a preview box.

2.2. The templates Option

Using the **templates** option gives you access to predefined styles for theorems. To use them, insert the **Set Keys** layout, as before, and in the keys list write a name of one of the styles. For example, here is a theorem with the **fancycolorcoded** style (for a full list of styles see [subsection 3.4](#))

¹Credit to thmtools

Theorem 2.3 (Pythagoras). *In any right triangle, the area of the square whose side is the hypotenuse (the side opposite the right angle) is equal to the sum of the areas of the squares whose sides are the two legs (the two sides that meet at a right angle).*

2.3. List of Theorems

To print a list of theorems go to LyX's environment selection combobox, select the List of Theorems layout, and set the keys in the keys inset. Here are two short examples:

List of Theorems

2.1. Theorem (Pythagoras)	2
2.2. Theorem (Pythagoras)	3
2.3. Theorem (Pythagoras)	4

Now I will change the list format with the swapnumber key, and change the title with the title key

My Title

Theorem 2.1 (Pythagoras)	2
Theorem 2.2 (Pythagoras)	3
Theorem 2.3 (Pythagoras)	4

For a full list of keys and their description, see [subsection 3.3](#).

3. Detailed Information

In the following section, if a key description is titled in violet color, it is similar to a key from `thmtools`, if it is green, it's a new key defined in `fancythm`.

3.1. Theorems Keys

- headfont** **Value: `TEX` code.** Executed just before the head of the theorem is typeset, inside a group. Intended use it to put font switches here.
- notefont** **Value: `TEX` code.** Executed just before the note in the head is typeset, inside a group. Intended use it to put font switches here. Formatting also applies to the braces around the note.
- bodyfont** **Value: `TEX` code.** Executed before the begin part of the theorem ends, but before all afterheadhooks. Intended use it to put font switches here.

headpunct **Value:** **T_EX** code, usually a single character. Put at the end of the theorem’s head, prior to linebreaks or indents.

headformat **Value:** **L^AT_EX** code, using the special placeholders `\NUMBER`, `\NAME` and `\NOTE`, which correspond to the (formatted, including the braces for `\NOTE` etc.) three parts of a theorem’s head. This can be used to override the usual style “1.1 Theorem (Foo)”, for example to let the numbers protrude in the margin or put them after the name.

! • The **headformat** key does not accept the keywords **margin** and **swapnumber** as it would with **thmtools**

postheadspace **Value:** **a length or a glue (with units).** Horizontal space inserted after the entire head of the theorem, before the body. Does probably not apply (or make sense) for styles that have a line-break after the head.

headindent **Value:** **a length or a glue (with units).** Horizontal space inserted before the head. Some publishers like `\parindent` here for remarks, for example.

title **Value:** **T_EX** code. The title of the theorem.

name Same as **title**

heading same as **title**

preheadhook **Value:** **L^AT_EX** code. This code will be executed at the beginning of the environment, even before vertical spacing is added and the head is typeset. However, it is already within the group defined by the environment.

postheadhook **Value:** **L^AT_EX** code. This code will be executed after the call to the original `begin-theorem` code. Note that all backends seem to delay typesetting the actual head, so code here should probably enter horizontal mode to be sure it is after the head, but this will change the spacing/wrapping behaviour if your body starts with another list.

prefoothook **Value:** **L^AT_EX** code. This code will be executed at the end of the body of the environment.

postfoothook **Value:** **L^AT_EX** code. This code will be executed at the end of the environment, even after eventual vertical spacing, but still within the group defined by the environment.

refname	Value: one string, or two strings separated by a comma (no spaces). This is the name of the theorem as used by <code>\autoref</code> , <code>\cref</code> and friends. If it is two strings, the second is the plural form used by <code>\cref</code> . Default value is the value of name .
leftnotebrace	Value: one character, the opening symbol to use around a theorem's note.
rightnotebrace	Value: one character, the closing symbol to use around a theorem's note.
spaceabove	Value: a length or a glue (with units). Vertical space above the theorem, possibly discarded if the theorem is at the top of the page.
spacebelow	Value: a length or a glue (with units). Vertical space after the theorem, possibly discarded if the theorem is at the top of the page.
qed	Value: one character, the closing mark of the theorem (as with proof and <code>\qedsymbol</code>).
parent	Value: a counter name. The theorem will be reset whenever that counter is incremented. Usually, this will be a sectioning level, chapter or section . If the input is not a counter name, the theorem will become independent.
numberwithin	Same as parent .
within	Same as parent .
numbered	Value: one of the keywords yes or no. The theorem will be numbered, or not numbered.
sibling	Value: a counter name. The theorem will use this counter for numbering. Usually, this is the name of another theorem environment. If the input is not a counter name, the theorem will become independent.
numberlike	Same as sibling .
sharenumber	Same as sibling .

The following keys are not supported: `style`, `Refname`, `shaded`, `thmbox`, `,notebraces` (replaced with `leftnotebrace` and `rightnotebrace`), `mdframed`.

3.2. Layouts Information

Environment Name	Layout Name	Default title	Default headfont	Default bodyfont
thm	Theorem	Theorem	\bfseries	\itshape
thm*	Theorem*	Theorem	\bfseries	\itshape

Table: Names and default fonts of the environments

headpunct={.}	postheadspace=1em	headindent=0pt
preheadhook=<empty>	postheadhook=<empty>	prefoothook=<empty>
postfoothook=<empty>	rightnotebrace=)	leftnotebrace=(
spaceabove=6pt	spacebelow=6pt	numberwithin=section
sibling=<empty>	qed=<empty>	notefont=<empty>
refname=theorems title numbered=true/false (unstarred/starred) headformat=\NAME\ \NUMBER\NOTE/ \NAME\NOTE (unstarred/starred)		

Table: Default keys values

3.3. List of Theorems Keys

title	Value: title of \listoftheorems. The default is stored in the macro \listtheoremname and is initially “List of Theorems”.
ignore	Value: comma seperated list of theorem environment names. Filter out things by environment names. Default value is list of all defined theorem environments.
ignoreall	Ignore every theorem environment. This key is usually followed by keys show and onlynamed.
show	Value: comma seperated list of theorem environment names. Leave theorems that belong to specified list and filter out others. Default value is list of all defined theorem environments.
showall	The opposite effect of ignoreall.
onlynamed	Value: comma seperated list of theorem environment names. Leave things that are given an optional argument and belong to specified list, and filter out others. Default value is list of all defined theorem environments.
swapnumber	Value: true or false. If set to true, numbers will appear after the theorem name in the list. Initially false and default value is true.
numwidth	Value: a length or a glue (with units). If swapnumber=false, the theorem number is typeset in a box of of width numwidth. Initially 1.5pc for AMS classes and 2.3em for others.
columns	Value: a positive integer. If set to an integer bigger than 1, the list of theorems will be printed in a multicol environment with number of columns as the input.

notitle Value: **true or false**. Is set to true, the list of theorems will print with no title. Initially false.

3.4. Keys - templates option

The following is the full list of styles defined with the **templates** option:

default, named, colorcoded, fancycolorcoded, thmbox, margins, tcb, tcbribbon, tcbdiamond, and bclogo.

! Actually, the keys default, named, and margins are defined in the basic module (without the **templates** option).

To use each of these styles, write it's name in the key list in the **Set Keys** layout. Non of these keys accept value, except margins which accepts a length which represent the distance from the title to the body of the theorem, and thmbox which can get three values: S, M, L (for small, medium and large).

To see all the styles of all the layouts see the file **test_fancythm.pdf**.

In addition to all the style keys, the **template** option adds three additional keys:

color Value: **name of a defined color color, or a mix of several, using xcolor syntax**. It will define the color of all the styles related to the theorem.

beginstyle Value: **L^AT_EX code**. This code will be executed at the beginning of the environment, but after vertical spacing is added and the head is typeset.

endstyle Value: **L^AT_EX code**. This code will be executed at the end of the environment, but before eventual vertical spacing.

4. Support for Bilingual And RTL Documents

4.1. RTL Documents

As this module uses **amsthm**, it is recommended to compile RTL files that includes the Fancy Theorem module with XeLaTeX and polyglossia, as there are known issues with babel and amsthm. Also, all the non-symmetric styles defined in the **templates** option will not display correctly, unless the **bidi** package is used.

4.2. Bilingual Documents

the module will support different fonts for different languages in the theorems environments by default if you use polyglossia, otherwise there would be a need to specify it manually with the relevant font keys.

A. Documentation of fancythm

this section is incomplete and will be uploaded soon.
