Description of the module Fancy Theorems

Udi Fogiel

Abstract

With the module Fancy Theorems you can modify all the theorems layouts output appearance (except the proof and case layouts), using a key-val syntax much like in thmtools. All the theorems environments are defined using the LATEX package fancythm, which rely heavily on the LATEX package thmtools . It is recommended to read some of thmtools documentation.

1. Preparation

1.1. Installation

Firstly, manually install the fancythm package. The installation procedure is dependent on your LATEX distribution, so I won't explain how to do so here (it will probably just require you to copy the fancythm folder to some directory, and then tell your latex LATEX distribution that you added a new folder to it's directories).

To install the module Fancy Theorems, move the file fancythm.module to the layouts folder in LyX's user directory (which can be found in Help \triangleright About Lyx.). After that reconfigure LyX via Tools \triangleright Reconfigure, and restart LyX.

1

Note that the LATEX package fancythm requires the packages amsthm, thmtools and multicols. If the templates option is used, fancythm loads xcolor, tikz with the decorations.pathmorphing and shadows libraries, varwidth, and tcolorbox with the most option. It is recommended to check that all of these packages are installed.

1.2. Loading The Module

At first load the module $Fancy\ Theorems$ in the document settings of your file, via Documents \triangleright Settings \triangleright Modules.

If you want to use the **templates** option, write "templates" in the document class options in the document settings of your file.

2. Basics

2.1. Designing Theorems

Suppose you would like to state the Pythagorean theorem in your document. To do so, go to L_YX's environment selection combobox, select the Theorem layout and write the theorem's content (if you would to write an optional note, go to Insert > Optional Note, or press Alt+A 1).

Theorem 2.1 (Pythagoras). In any right triangle, the area of the square whose side is the hypotenuse (the side opposite the right angle) is equal to the sum of the areas of the squares whose sides are the two legs (the two sides that meet at a right angle).

To change the appearance of the theorems in the output PDF file insert the Set Keys layout via Insert > Custom Insets > Set Keys, in the argument inset (called envs) write a comma separated list of all the environments names that you want to change (for a list of all the environments names see subsection 3.2), and in the inset itself write the keys with the appropriate values. For example, we will change the note braces to be square brackets, we will add a symbol to mark the end of the theorem and add more vertical space before the theorem.

Now we should be able to see the changes in all the following theorems (with environment name thm).

Theorem 2.2 [Pythagoras]. In any right triangle, the area of the square whose side is the hypotenuse (the side opposite the right angle) is equal to the sum of the areas of the squares whose sides are the two legs (the two sides that meet at a right angle).

The latex command of that layout is \setfancythmkeys{<envs>}{<key=val>}, where <envs> is a comma separated list of all the environments names that you want to change, and <key=val> is a comma separated list of the keys you want to change. In addition, <envs> accepts the keywords all, reg, and strd to apply the changes to all environments, all the unstarred variants, or all the starred variants.

The following diagram¹ demonstrates some of the possible theorems keys.

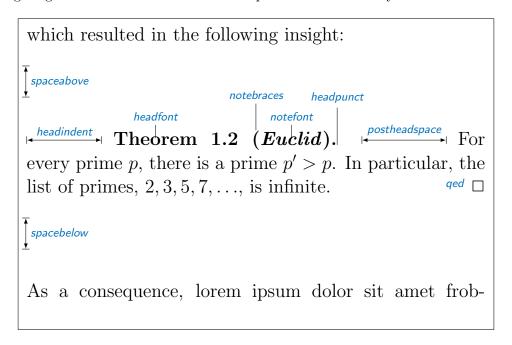

Figure: Settable parameters of a theorem style.

For a full list of keys and their description, see subsection 3.1.

There is an option to use preview box (via Insert > Preview) with the theorems layouts, but, to see the changes that you applied you need to include the Set Keys layout in the preview box, or, set the keys in the preamble (and make sure that Tools > Preference > Look & Feel > Display > Instant Preview is on).

For example, this paragraph is written with the Remark* layout (its keys are set in the preamble) inside a preview box.

2.2. The templates Option

Using the **templates** option gives you access to predefined styles for theorems. To use them, insert the Set Keys layout, as before, and in the keys list write a name of one of the styles. For example, here is a theorem with the fancycolorcoded style (for a full list of styles see subsection 3.4)

¹Credit to thmtools

Theorem 2.3 (Pythagoras). In any right triangle, the area of the square whose side is the hypotenuse (the side opposite the right angle) is equal to the sum of the areas of the squares whose sides are the two legs (the two sides that meet at a right angle).

2.3. List of Theorems

To print a list of theorems go to LyX's environment selection combobox, select the List of Theorems layout, and set the keys in the keys inset. Here are two short examples:

List of Theorems

2.1.	Theorem (Pythagoras)	2
2.2.	Γheorem (Pythagoras)	3
2.3.	$\Gamma \text{heorem (Pythagoras)} \dots \dots$	4

Now I will change the list format with the swapnumber key, and change the title with the title key

My Title

Theorem 2.	1 (Pythagoras)	 				 		 								2
Theorem 2.	2 (Pythagoras)	 				 		 			 					3
Theorem 2	3 (Pythagoras)															Δ

For a full list of keys and their description, see subsection 3.3.

3. Detailed Information

In the following section, if a key description is titled in violet color, it is similar to a key from thmtools, if it is green, it's a new key defined in fancythm.

3.1. Theorems Keys

headfont Value: TeX code. Executed just before the head of the theorem is typeset, inside a group. Intended use it to put font switches here.

Value: TEX code. Executed just before the note in the head is typeset, inside a group. Intended use it to put font switches here. Formatting also applies to the braces around the note.

Value: TeX code. Executed before the begin part of the theorem ends, but before all afterheadhooks. Intended use it to put font switches here.

headpunct Value: TeX code, usually a single character. Put at the end of

the theorem's head, prior to linebreaks or indents.

headformat Value: LATEX code, using the special placeholders \NUMBER,

\NAME and \NOTE, which correspond to the (formatted, including the braces for \NOTE etc.) three parts of a theorem's head. This can be used to override the usual style "1.1 Theorem (Foo)", for example to let the numbers protrude in the margin or put them

after the name.

th

The **headformat** key does not accept the keywords **margin** and **swapnumber** as it would with thmtools

postheadspace Value: a length or a glue (with units). Horizontal space

inserted after the entire head of the theorem, before the body. Does probably not apply (or make sense) for styles that have a

line-break after the head.

headindent Value: a length or a glue (with units). Horizontal space

inserted before the head. Some publishers like \parindent here

for remarks, for example.

title Value: TEX code. The title of the theorem.

name Same as title

heading same as title

preheadhook Value: LATEX code. This code will be executed at the beginning

of the environment, even before vertical spacing is added and the head is typeset. However, it is already within the group defined

by the environment.

postheadhook Value: LATEX code. This code will be executed after the call to

the original begin-theorem code. Note that all backends seem to delay typesetting the actual head, so code here should probably enter horizontal mode to be sure it is after the head, but this will change the spacing/wrapping behaviour if your body starts with

another list.

prefoothook Value: LATEX code. This code will be executed at the end of the

body of the environment.

postfoothook Value: LATEX code. This code will be executed at the end of the

environment, even after eventual vertical spacing, but still within

the group defined by the environment.

refname Value: one string, or two strings separated by a comma

(no spaces). This is the name of the theorem as used by \autoref, \cref and friends. If it is two strings, the second is the plural form used by \cref. Default value is the value of name.

leftnotebrace Value: one character, the opening symbol to use around a the-

orem's note.

rightnotebrace Value: one character, the closing symbol to use around a theo-

rem's note.

spaceabove Value: a length or a glue (with units). Vertical space above

the theorem, possibly discarded if the theorem is at the top of the

page.

spacebelow Value: a length or a glue (with units). Vertical space after

the theorem, possibly discarded if the theorem is at the top of the

page.

qed Value: one character, the closing mark of the theorem (as with

proof and \qedsymbol).

parent Value: a counter name. The theorem will be reset whenever

that counter is incremented. Usually, this will be a sectioning level, chapter or section. If the input is not a counter name, the

theorem will become independent.

number within Same as parent.

within Same as parent.

numbered Value: one of the keywords yes or no. The theorem will be

numbered, or not numbered.

sibling Value: a counter name. The theorem will use this counter for

numbering. Usually, this is the name of another theorem environment. If the input is not a counter name, the theorem will become

independent.

numberlike Same as sibling.

sharenumber Same as sibling.

The following keys are not supported: style, Refname, shaded, thmbox, ,notebraces (replaced with leftnotebrace and rightnotebrace), mdframed.

3.2. Layouts Information

Environment Name	Layout Name	Default title	Default headfont	Default bodyfont

sibling= <empty></empty>	qed= <empty></empty>	notefont= <empty></empty>

refname=theorems title numbered=true/false (unstarred/starred) headformat=\NAME\\\NUMBER\NOTE/\\\NAME\\\NOTE (unstarred/starred)

Table: Default keys values

3.3. List of Theorems Keys

title Value: title of \listoftheorems. The default is stored in the macro \listtheoremname and is initially "List of Theorems".

ignore Value: comma seperated list of theorem environment names. Filter out things by environment names. Default value is list of all defined theorem environments.

ignoreall Ignore every theorem environment. This key is usually followed by keys show and onlynamed.

show Value: comma seperated list of theorem environment names. Leave theorems that belong to specified list and filter out others. Default value is list of all defined theorem environments.

showall The opposite effect of ignoreall.

onlynamed Value: comma seperated list of theorem environment names. Leave things that are given an optional argument and belong to specified list, and filter out others. Default value is list of all defined theorem environments.

Value: true or false. If set to true, numbers will appear after the theorem name in the list. Initially false and default value is true.

numwidth Value: a length or a glue (with units). If swapnumber=false, the theorem number is typeset in a box of of width numwidth. Initially 1.5pc for AMS classes and 2.3em for others.

Columns Value: a positive integer. If set to an integer bigger than 1, the list of theorems will be printed in a multicol environment with number of columns as the input.

notitle Value: true or false. Is set to true, the list of theorems will print with no title. Initially false.

3.4. Keys - templates option

The following is the full list of styles defined with the **templates** option:

default, named, colorcoded, fancycolorcoded, thmbox, margins, tcb, tcbribbon, tcbdiamond, and bclogo.

Actually, the keys default, named, and margins are defined in the basic module (without the templates option).

To use each of these styles, write it's name in the key list in the Set Keys layout. Non of these keys accept value, except margins which accepts a length which represent the distance from the title to the body of the theorem, and thmbox which can get three values: S, M, L (for small, medium and large).

To see all the styles of all the layouts see the file test_fancythm.pdf.

In addition to all the style keys, the **template** option adds three additional keys:

Value: name of a defined color color, or a mix of several, using xcolor syntax. It will define the color of all the styles related to the theorem.

Value: LATEX code. This code will be executed at the beginning of the environment, but after vertical spacing is added and the head is typeset.

endstyle Value: LATEX code. This code will be executed at the end of the environment, but before eventual vertical spacing.

4. Support for Bilingual And RTL Documents

4.1. RTL Documents

As this module uses **amsthm**, it is recommended to compile RTL files that includes the Fancy Theorem module with XeLaTeX and polyglossia, as there are known issues with babel and amsthm. Also, all the non-symmetric styles defined in the **templates** option will not display correctly, unless the **bidi** package is used.

4.2. Bilingual Documents

the module will support different fonts for different languages in the theorems environments by default if you use polyglossia, otherwise there would be a need to specify it manually with the relevant font keys.

A. Documentation of fancythm

this section is incomplete and will be uploaded soon.
